# Coordinate system

- Global coordinate system: often taken to be attached to Earth, though it could as well be attached to another ground plane such as the frame of an automobile (GCS –  $X, Y$ ). Also called as the absolute coordinate system
- Local coordinate system are typically attached to a link to some point of interest. This might be a pin joint, a centre of gravity, or a line of centres of a link (LCS –  $x, y$ )

# Position

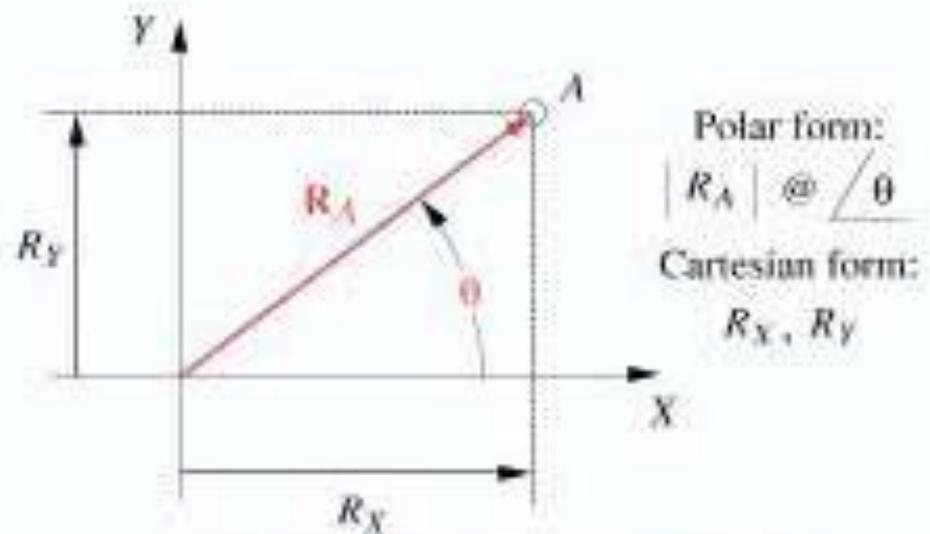

- A position of a point in the plane can be defined by the use of position vector
- The choice of reference axis is arbitrary and is selected to suit the observer
- A two dimensional vector has two attributes, which can be expressed in either polar or Cartesian coordinates
- The polar form provides the magnitude and angle of the vector
- The Cartesian form provides the  $X$  and  $Y$  component of the vector

# Relationship between polar and Cartesian

$$R_A = \sqrt{R_X^2 + R_Y^2}$$

$$\theta = \arctan\left(\frac{R_Y}{R_X}\right)$$

(a) Global coordinate system XY

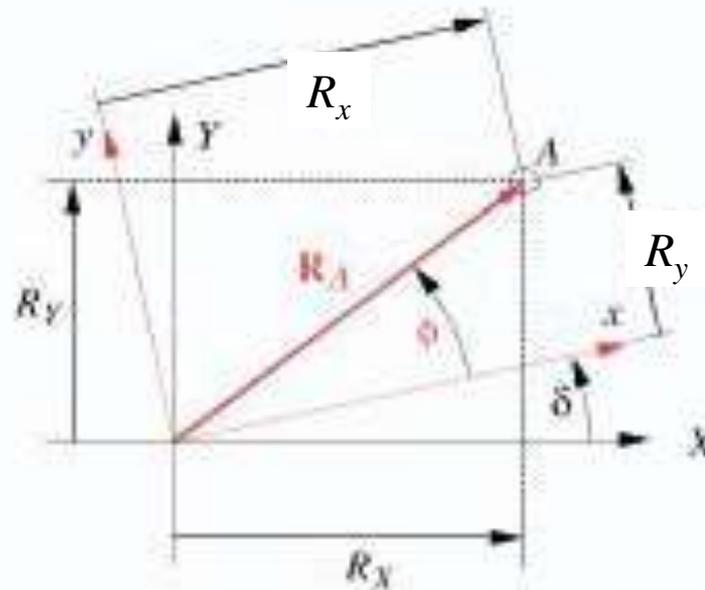

# Coordinate Transformation

- It is often necessary to transform the coordinates of a point defined in one coordinate system to coordinate system in another
- If the position of point A is expressed in the local  $xy$  system as  $R_x, R_y$  and it is desired to transform its coordinates to  $R_X, R_Y$  in the global  $XY$  system, the equations are:

$$R_X = R_x \cos \delta - R_y \sin \delta$$

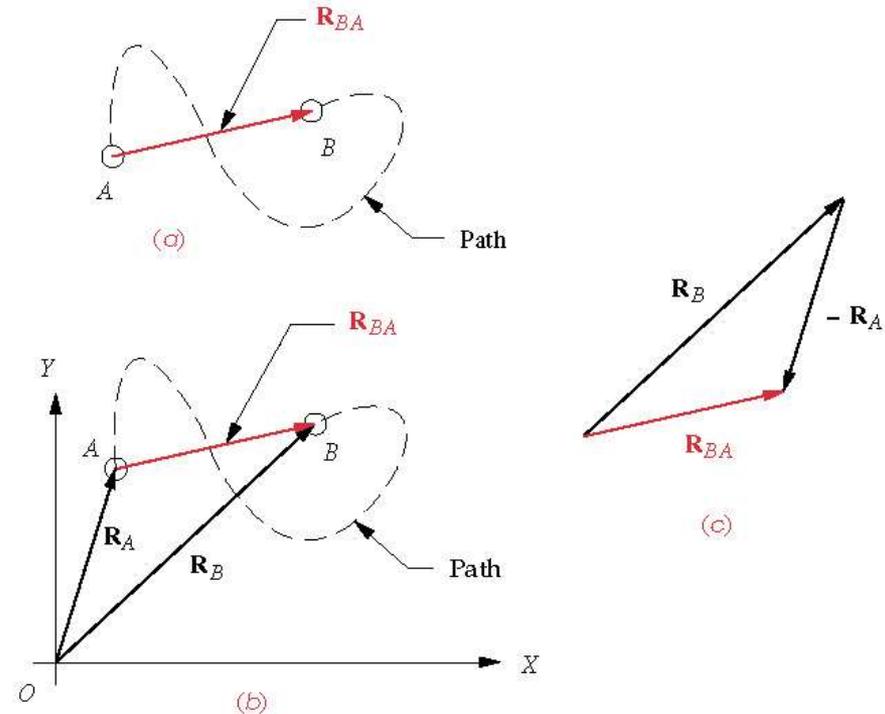

$$R_Y = R_x \sin \delta + R_y \cos \delta$$

Polar form:  
 $|R_A| @ \angle \theta$   
Cartesian form:  
 $R_x, R_y$

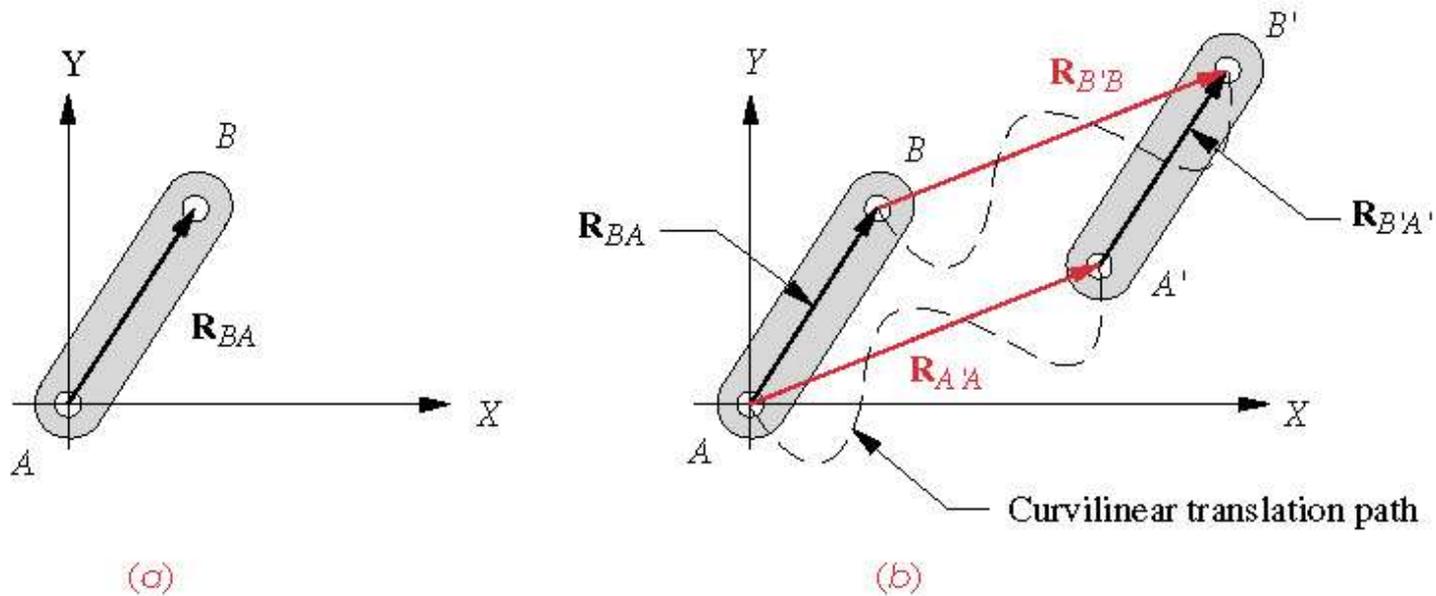

# Displacement

- Displacement of a point is the change in its position and can be defined as the straight line distance between the initial and final position of a point which has moved in the reference frame
- The position of B with respect to A is equal to the (absolute) position of B minus the (absolute) position of A, where absolute means with respect to global reference frame
- $R_{BA} = R_B - R_A$
- $R_{BA} = R_{BO} - R_{AO}$

# Translation

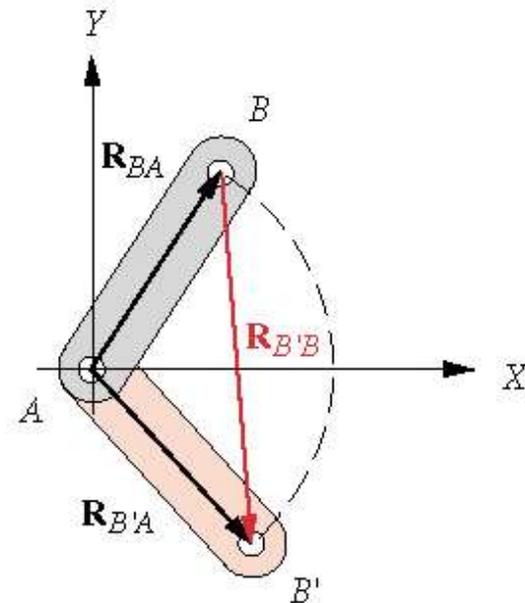

- All points on the body have the same displacement
- Note that translation need not be along a straight path
- If the path happens to be a straight line then its called the rectilinear translation, otherwise it is the curvilinear translation

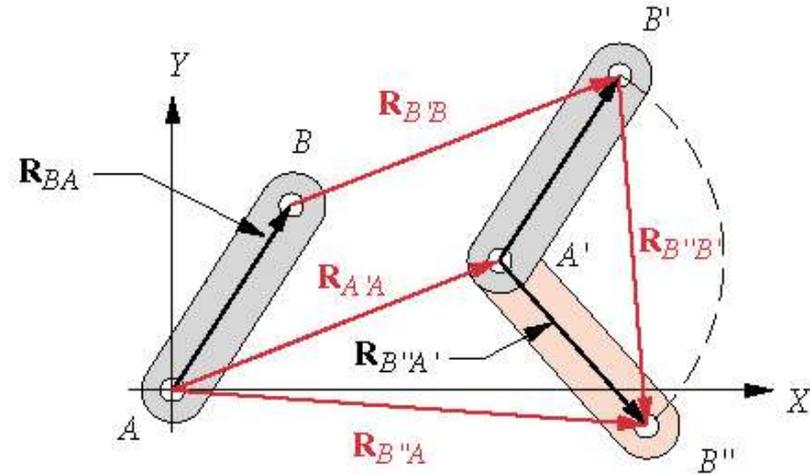

# Rotation

- Different points in the body undergo different displacements and thus there is a displacement difference between any two points chosen

# Complex motion

- Sum of translation and rotation components
- Total displacement = translation component + rotation component

# Theorems

- Euler's theorem:
  - The general displacement of a rigid body with one point fixed is a rotation about some axis
- Chasles' theorem:
  - Any displacement of a rigid body is equivalent to the sum of a translation of any one point on that body and a rotation of the body about an axis through that point

# Position Analysis Methods

- Algebraic
- Graphical
- Vectors
- Complex Numbers

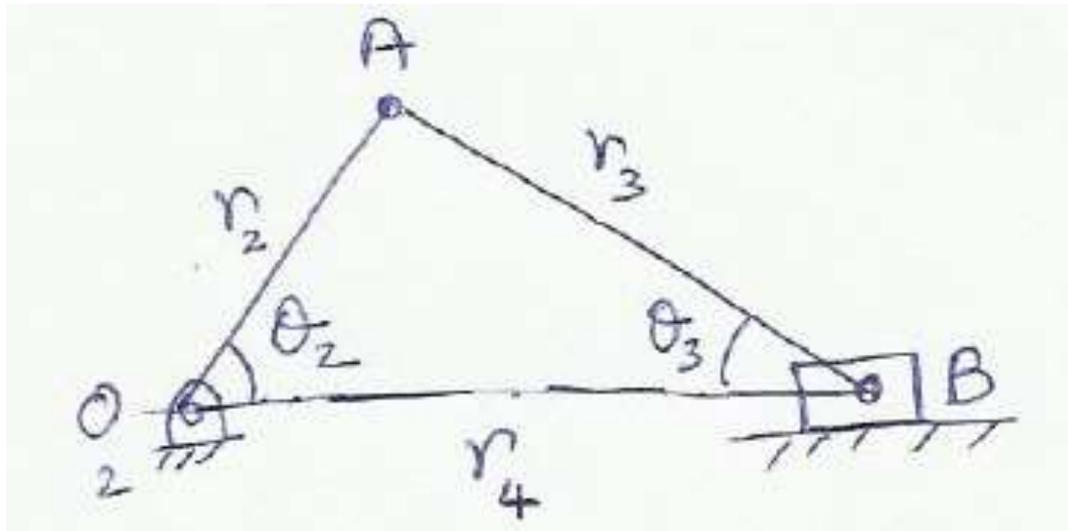

We will start with Algebraic Method and solve some examples on the white board

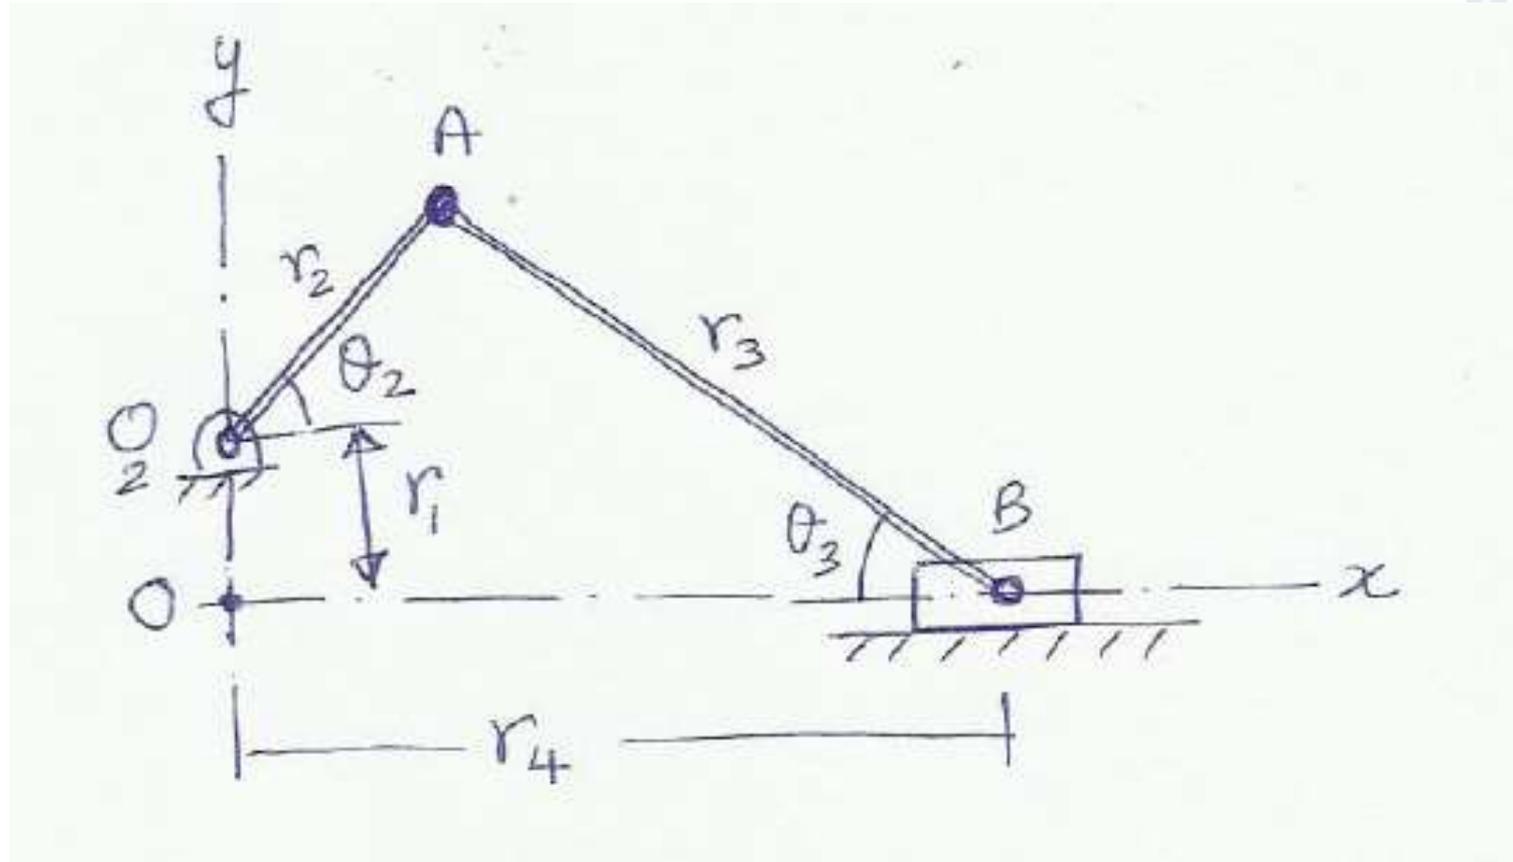

**We will consider planner mechanism  
with pin joints and sliding joint**

# Slider Crank Mechanism – Position Analysis

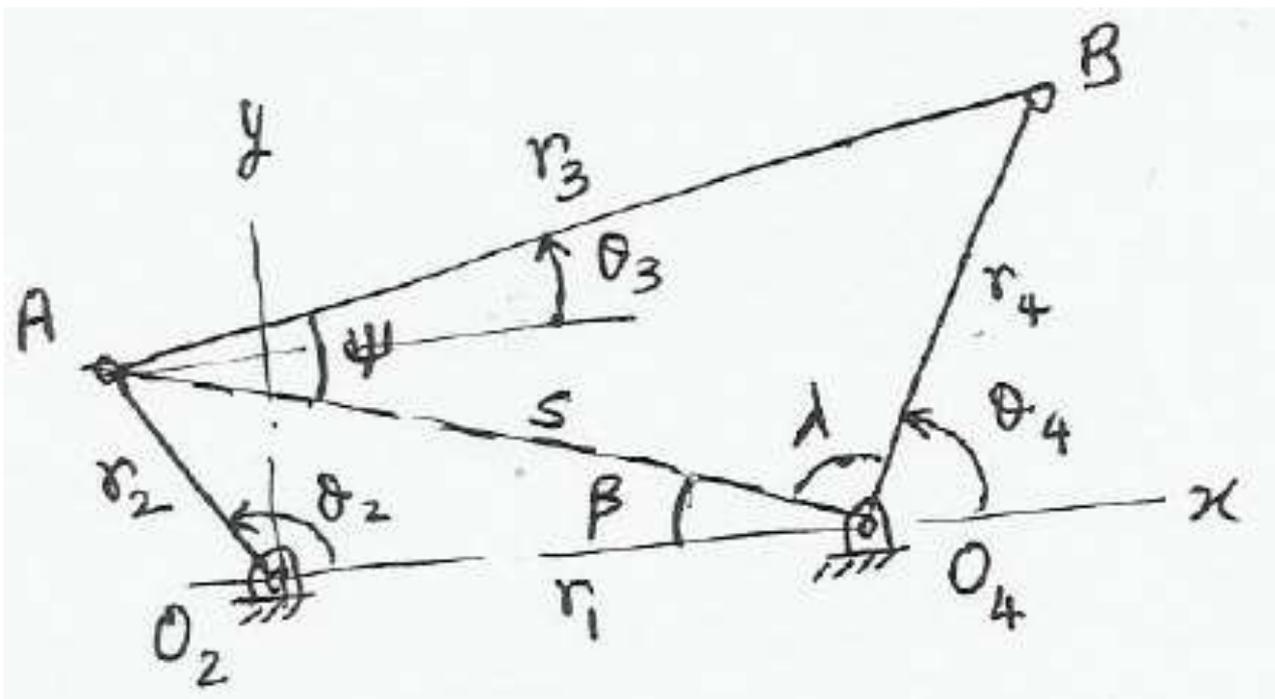

# Slider Crank Mechanism with an offset – Position Analysis

# Position Analysis 4 Bar Mechanism

# Graphical Methods

- Use some of the drawing tools
