

Balanced Incomplete Block Design

BIBD

Randomized Incomplete Block Design

These are randomized block designs in which every treatment is not present in every block.

The experimenter is not be able to run all the treatment combinations in each block because:

- Shortages of Experimental Apparatus or Facilities
- The Physical Size of the Block

BIBD Model Adequacy

Example

Balanced Incomplete Block Design (BIBD)

An incomplete block design in which any two treatments appear together an equal number of times. This happens when all treatment comparisons are equally important and the treatment combinations used in each block should be selected in a balanced manner.

Balanced Incomplete Block Design

BIBD

Suppose that there are α treatments and that each block can hold exactly k where ($k < \alpha$) treatments. A balanced incomplete block design may be constructed by taking binomial coefficient of α and k blocks and assigning a different combination of treatments to each block.

BIBD Model Adequacy

Assume that there are α treatments and b blocks. In addition, assume that each block contains k treatments, that each treatment occurs r times in the design (or is replicated r times), and that there are $N = \alpha r = bk$ total observations. Furthermore, the number of times each pair of treatments appears in the same block is

$$\lambda = \frac{r(k - 1)}{a - 1}$$

Example

If $\alpha = b$, the design is said to be **symmetric**.

Balanced Incomplete Block Design

BIBD

The statistical model for the BIBD

$$y_{ij} = \mu + \tau_i + \beta_j + \epsilon_{ij}$$

where y_{ij} is the i th observation in the j th block, μ is the overall mean, τ_i is the effect of the i th treatment, β_j is the effect of the j th block, and ϵ_{ij} is the NID $(0, \sigma^2)$ random error

The BIBD ANOVA Table

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	F_0
Treatments (adjusted)	$\frac{k \sum Q_i^2}{\lambda a}$	$a - 1$	$\frac{SS_{\text{Treatments(adjusted)}}}{a - 1}$	$F_0 = \frac{MS_{\text{Treatments(adjusted)}}}{MS_E}$
Blocks	$\frac{1}{k} \sum y_j^2 - \frac{y_{..}^2}{N}$	$b - 1$	$\frac{SS_{\text{Blocks}}}{b - 1}$	
Error	SS_E (by subtraction)	$N - a - b + 1$	$\frac{SS_E}{N - a - b + 1}$	
Total	$\sum \sum y_{ij}^2 - \frac{y_{..}^2}{N}$	$N - 1$		

BIBD Model Adequacy

Example

Balanced Incomplete Block Design

BIBD

$$SS_T = \sum_i \sum_j y_{ij}^2 - \frac{y_{..}^2}{N}$$

$$SS_T = SS_{\text{Treatments(adjusted)}} + SS_{\text{Blocks}} + SS_E$$

$$SS_{\text{Blocks}} = \frac{1}{k} \sum_{j=1}^b y_j^2 - \frac{y_{..}^2}{N}$$

$$SS_{\text{Treatments(adjusted)}} = \frac{k \sum_{i=1}^a Q_i^2}{\lambda a}$$

$$Q_i = y_{i.} - \frac{1}{k} \sum_{j=1}^b n_{ij} y_{.j} \quad i = 1, 2, \dots, a$$

BIBD Model Adequacy

Example

Rejection Criteria

$$F_0 > F_{\alpha, (a-1), (N-a-b+1)}$$

BIBD Model Adequacy

BIBD

A chemical engineer thinks that the time of reaction for a chemical process is a function of the type of catalyst employed. Four catalysts are currently being investigated. The experimental procedure consists of selecting a batch of raw material, loading the pilot plant, applying each catalyst in a separate run of the pilot plant, and observing the reaction time. Because variations in the batches of raw material may affect the performance of the catalysts, the engineer decides to use batches of raw material as blocks. However, each batch is only large enough to permit three catalysts to be run. Therefore, a randomized incomplete block design must be used. The balanced incomplete block design for this experiment, along with the observations recorded in the following table.

BIBD Model Adequacy

Example

Treatment (Catalyst)	Block (Batch of Raw Material)				y_i
	1	2	3	4	
1	73	74	—	71	218
2	—	75	67	72	214
3	73	75	68	—	216
4	75	—	72	75	222
y_j	221	224	207	218	$870 = y_{..}$

BIBD Model Adequacy

$$a = 4, b = 4, k = 3, \lambda = 2 : N = 12$$

BIBD

$$\begin{aligned} SS_T &= \sum_i \sum_j y_{ij}^2 - \frac{y_{..}^2}{12} \\ &= 63,156 - \frac{(870)^2}{12} = 81.00 \end{aligned}$$

BIBD Model Adequacy

$$\begin{aligned} SS_{\text{Blocks}} &= \frac{1}{3} \sum_{j=1}^4 y_j^2 - \frac{y_{..}^2}{12} \\ &= \frac{1}{3} [(221)^2 + (207)^2 + (224)^2 + (218)^2] - \frac{(870)^2}{12} = 55.00 \end{aligned}$$

Example

$$Q_1 = (218) - \frac{1}{3}(221 + 224 + 218) = -9/3$$

$$Q_2 = (214) - \frac{1}{3}(207 + 224 + 218) = -7/3$$

$$Q_3 = (216) - \frac{1}{3}(221 + 207 + 224) = -4/3$$

$$Q_4 = (222) - \frac{1}{3}(221 + 207 + 218) = 20/3$$

BIBD Model Adequacy

BIBD

$$SS_{\text{Treatments(adjusted)}} = \frac{k \sum_{i=1}^4 Q_i^2}{\lambda a}$$

$$= \frac{3[(-9/3)^2 + (-7/3)^2 + (-4/3)^2 + (20/3)^2]}{(2)(4)} = 22.75$$

BIBD Model Adequacy

$$SS_E = SS_T - SS_{\text{Treatments(adjusted)}} - SS_{\text{Blocks}}$$

$$= 81.00 - 22.75 - 55.00 = 3.25$$

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	F_0	P-Value
Treatments (adjusted for blocks)	22.75	3	7.58	11.66	0.0107
Blocks	55.00	3	—		
Error	3.25	5	0.65		
Total	81.00	11			

Example

$$F_{\alpha, (a-1), (N-a-b+1)} = F_{0.05, 3, 5} = 5.41$$

BIBD

An engineer is studying the mileage performance characteristics of five types of gasoline additives. In the road test he wishes to use cars as blocks; however, because of a time constraint, he must use an incomplete block design. He runs the balanced design with the five blocks that follow. Analyze the data from this experiment (use $\alpha = 0.05$) and draw conclusions

BIBD Model Adequacy

Additive	Car
